Abstract

The construction material on a plant basis PB (preferably miscantus) contains a binder and a mineralizer composed of a 5 defined mixture M2 of calcium carbonate CaCO3 and magnesium carbonate MgCO₃ that is prepared in an application-oriented manner, thereby resulting in a substantial improvement of its chemical, physical, and mechanical properties. The weight proportions of the components constituting said 10 mixture M2 are comprised between approx. 60 % and approx. 95 %, preferably between 2/3 and 9/10, for the CaCO₃, and between approx. 5 % and approx. 40 %, preferably between 1/10 and 1/3, for the MgCO₃. The method for producing said construction material is rationalized by previously admixing 15 the mineralizer to the binder, preferably Portland cement of strength class 52.5, directly at the binder plant according to determined specifications to obtain a mixture M1. The weight proportions of the components constituting the mixture M1 are comprised between approx. 50 % and approx. 20 90 %, preferably between 6/10 and 4/5, for the binder, and between approx. 10 % and approx. 50 %, preferably between 1/5 and 4/10, for the mineralizer. In order to improve the solidification process, a fungicidal preparation is added to the mixing water. A universal construction material allowing 25 innumerable applications can be produced from the aggregate {PB + M1}. The range of applications is further enlarged by adding another application-oriented mixture M3 to said aggregate in defined proportions (e.g. gypsum for producing quick-assembly structural panels) or a flow agent in order 30 to allow an extrusion method (e.g. for producing bar-shaped elements)).
